Introduction to Computer Security

Lecture 7: Password Cracking

Instructor: Dan Barowy
Williams

Topics

Crypto refresher

Password database attacks

Hash chains

Your to-dos

1. Read *Trading Time for Space* **for Monday, 10/2.**
2. Read *Making a Faster Cryptanalytic Time-Memory Tradeoff* **for Thu, 10/5.**
 - i. Please take notes.
3. Project part 1 due **Sunday, 10/1.**

Cryptography refresher

Encryption is the **process of encoding a message** so that it can be read only by the sender and the **intended recipient**.

- A **plaintext** p is the original, unobfuscated data. This is information you want to protect.
- A **ciphertext** c is encoded, or encrypted, data.
- A **cipher** f is an algorithm that converts **plaintext** to **ciphertext**. We sometimes call this function an **encryption function**.
 - * More formally, a cipher is a function from plaintext to ciphertext, $f(p)=c$. The properties of this function determine what kind of encryption scheme is being used.
- A **sender** is the person (or entity) who enciphers or encrypts a message, i.e., the party that converts the plaintext into ciphertext. $f(p)=c$
- A **receiver** is the person (or entity) who decipheres or decrypts a message, i.e., the party that converts the ciphertext back into plaintext. $f^{-1}(c)=p$

Why Stolen Password Databases are a Problem has a little more nuance.

A Common Attack

Entire password database **leaked** (bug; misconfiguration; theft by authorized personnel).

We keep password databases in **encrypted** form.

Password database attacks

- Random guessing attack
- Enumeration attack
- Dictionary attack
- Precomputed hash chain attack
- **Rainbow** table attack

Random guessing

```
for each entry in database:
    not_found = true
    // try until found
    while not_found:
        // random plaintext
        p = randPassword()
        // create ciphertext
        c = hash(p)
        // compare
        if c = entry.pwhash:
            print entry.pwhash, p
            not_found = false
```

Complexity?

Random guessing: complexity (one pw)

m = # of possible passwords

p = probability that random guess is correct

$$= 1/m$$

X = # guesses until success

$E[X] = (1-p)/p$ (geometric dist)

$$= m - 1$$

$O(m)$ average **per pw** $O(mn)$ average for **all pw**

Wait a sec...

Suppose password is: `password`

Hashes to `5f4dcc3b5aa765d61d8327deb882cf99`

Suppose we guess: `b1d78hdd`

Hashes to `310fca1c70732a8191d0199bddba3a97`

Clearly that was not the passwrld.

Does it make sense to guess: `b1d78hdd` again?

No! We should **remember** bad guesses.

Enumeration: slightly better

for each entry in database:

```
i = 0
not_found = true
// try until found or out of pt
while not_found && i < NUM_PT:
    // gen ith possible plaintext
    p = genPassword(i)
    // create ciphertext
    c = hash(p)
    // compare
    if c = entry.pwhash:
        print entry.pwhash, p
        not_found = false
    i++
```

Complexity?

Enumeration: complexity

m = # of possible passwords

Average guesses to find **one pw**:

$O(m/2)$

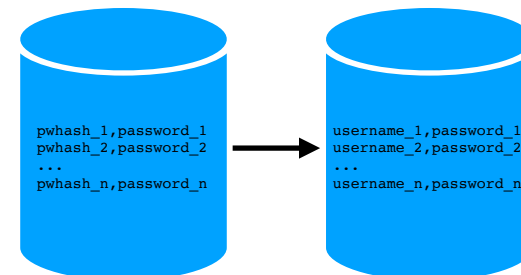

Average guesses to find **all pw**:

$O(n \times m/2)$

Dictionary attack

A **dictionary attack** is a form of **brute force attack** technique for **recovering passphrases** by systematically **trying all likely possibilities**, such as words in a dictionary.

Critically, a dictionary attack only tries each possibility once. It **trades space for time**.

Dictionary: much better

Ahead of time:

```
while i < NUM_PT:
    // gen ith possible plaintext
    p = genPassword(i)
    // create ciphertext
    c = hash(p)
    // save
    cracked_db[c] = p
```

Later:

```
for each entry in database:
    print cracked_db[entry.pwhash]
```

Complexity?

Dictionary attack: complexity

m = # of possible passwords

Time to compute dictionary:

$O(m)$

Time to lookup **one pw**:

$O(\log m)$

Time to lookup **all pws**:

$O(n \log m)$

Space needed:

$O(m)$

Activity: How much space?

It depends on the **number of possible passwords**.

Password scheme:

- Uppercase letters and numbers, except O and I.
- Up to 8 digits

How many passwords are there?

Activity: How much **space**?

m = # of passwords

$$= \sum_{k=1}^8 34^k = 1839908871710$$

≈ 1.8 trillion passwords

Suppose per-pw storage is **always 16 bytes**.
(8 bytes for ciphertext, 8 bytes for plaintext)

$16 \times (1.8 \times 10^{12})$ bytes

≈ 29 terabytes

Is this a **feasible attack**?

Is this a feasible attack?

space: ≈ 29 terabytes

Time?

Suppose I can generate 1 million pw/sec

$(1.8 \times 10^{12}) / 10^6 \approx (1.8 \times 10^6)$ seconds

≈ 21 days with one computer.

This is **definitely feasible!**

Precomputed hash chains

A **PCHC attack** is a form of **brute force attack** technique for **recovering passphrases** by systematically **trying all likely possibilities**, such as words in a dictionary.

Critically, a PCHC attack only tries each possibility once. It **trades space for time, but it compresses the database.**

Hash function

Suppose we have:

$f(p)=c$, a **cipher** that maps **plaintexts** to **ciphertexts**; in this case, a **hash function**.

Because f is a hash function, there is **no inverse function** such that $f^{-1}(f(p))=p$.

Hash function

Space of possible plaintexts

Space of possible hashes

8 digits, 0-9, a-f

64 digits, 0-9, a-f

→ hashing

plaintext: "9a55302d"

ciphertext: "4651f1799e5e36c878f3d980c59e94ae"

Reducer function

Suppose we have:

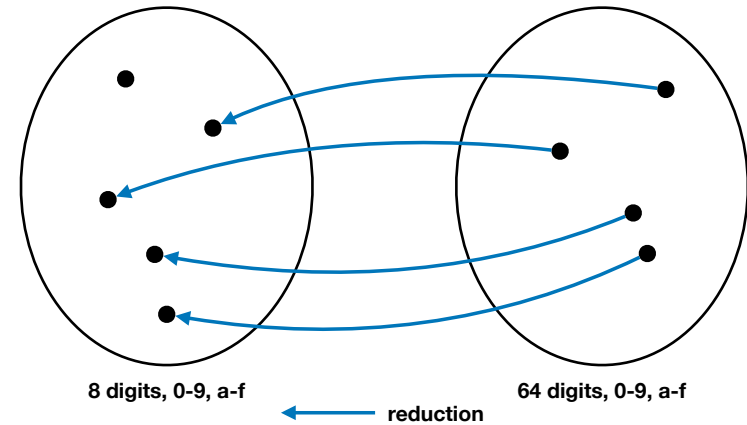

$r(c)=p$, that maps **ciphertexts** to **plaintexts**, called a **reducer**.

A reducer is **not the inverse** of the hash!

Reducer function

Space of possible plaintexts

Space of possible hashes

ciphertext: "4651f1799e5e36c878f3d980c59e94ae"

plaintext: "4651f179"

Reducer function properties

A reducer $r(c)=p$ only needs to satisfy a couple properties.

1. A reducer's output, p , should map to the same domain as the *input* of the hash function, $f(p)=c$ (i.e., plaintexts)

Reducer function properties

A reducer $r(c)=p$ only needs to satisfy a couple properties.

2. All plaintexts should be selected, given the space of ciphertexts, with equal probability.

Hash-reduce “round trip”

Space of possible plaintexts

Space of possible hashes

→ hashing
← reduction

plaintext: “9a55302d” ciphertxt: “4651f1799e5e36c878f3d980c59e94ae”
ciphertxt: “4651f1799e5e36c878f3d980c59e94ae” plaintext: “4651f179”

Hash chain

Space of possible plaintexts

Space of possible hashes

→ hashing
← reduction

Hash functions are not usually perfect

Space of possible plaintexts

Space of possible hashes

→ hashing
Collisions!

Hashes are guaranteed to collide

m: # of passwords

n: # of hashes

If $m > n$, we know that **at least** $(m-n)/m$ must collide.

“pigeonhole principle”

Thought experiment

Let's **suspend disbelief** for a moment.

1. Our **hash** function is **perfect**, chooses ciphertext with probability $1/m$.
2. Our **reducer** function is **perfect**, chooses plaintext with probability $1/m$.
3. The **combination** of hash function and reducer function is also **perfect**.

Real cryptographic hash functions are designed to approximate #1.

Real reducers can actually be perfect.

Thought experiment

What can we **do** with this information?

Thought experiment

- plaintexts
- ciphertexts

Suppose $f(p_i) = c_i$

Suppose $r(c_i) = p_{i-1}$ if $i > 1$ otherwise p_m

Thought experiment

- plaintexts
- ciphertexts

Such a scheme (a **hash chain**) lets us generate all plaintexts (and hashes) from a seed plaintext.

Only need to save the seed. **Drawbacks?**

Thought experiment: **drawbacks**

- Saving just the first password **buys us nothing**. On average, we have to compute $O(m/2)$ hash-reductions to find a password.
- **Hash functions collide!**

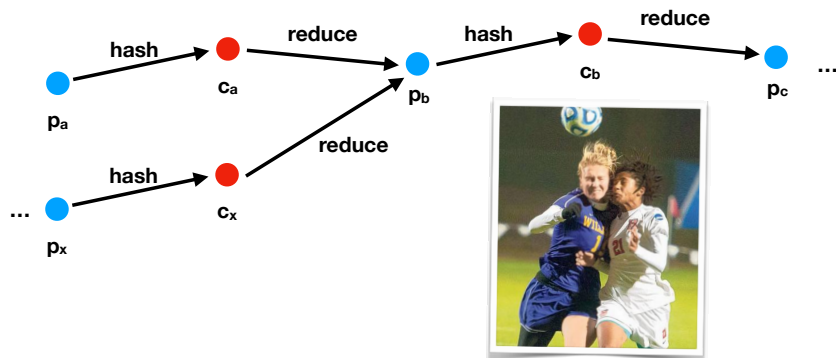

Collisions in a hash chain

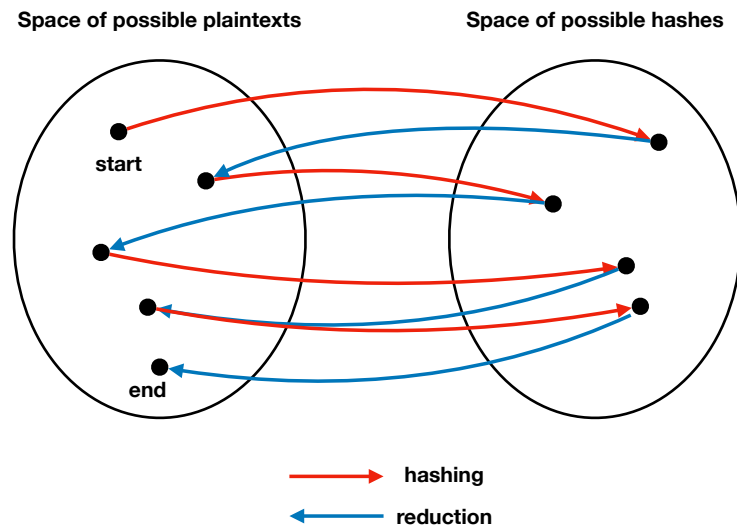

After the **collision**, the chain “**loops.**”
Collisions prevent us from enumerating the **entire space!**

Collisions in a hash chain

Reducers can produce collisions too!
This is what we mean by an **imperfect reducer**.

Hash chain

Hash chain of length k

We are going to chop up our long chain into **smaller chains** of length **k**.

A screenshot of a wikiHow article titled "How to Deal With a Police Polygraph Test". The article is co-authored by Clinton M. Sandvick, JD, PhD, a former civil litigator. It includes a detailed explanation of what a polygraph test is, how it works, and its reliability. The article also features a "Part 1" section titled "Understanding the Test" with an illustration of a person wearing a polygraph device.

Hash chain

Space of possible plaintexts

Space of possible hashes

→ hashing
← reduction

Hash chain of length 2

Space of possible plaintexts

Space of possible hashes

→ hashing
← reduction
