### \_\_\_\_ Turn-In Instructions \_\_\_\_

Turn in your work using the Github partner repository assigned to you. The name of the Github repository will have the form cs334lab9\_<your user name>-<your partner's user name>. For example, my repository might be cs334lab9\_dbarowy-wjannen. You should have received an invite to commit in the repository in your email. If you did not receive this email, please contact me right away!

For this assignment, your completed submission should consist of a project source code checkpoint. This is something you build yourself, from the ground up. You should use the class Parsers.fs library, and you may use any other code given to you during the course of this class.

This assignment is due on Sunday, May 1 by 10:00pm.

Sanity Check: Students sometimes submit incomplete assignments, accidentally forgetting to run git add for all of their files. Fortunately, there is an easy way to make sure that this does not happen to you. Before you are done, git clone your repository to a new folder and then try building/running everything. It only takes a couple minutes and can spare you from headaches later on.

# — Honor Code —

This is a <u>partner project lab</u>. You may work with another classmate if you wish, and you may co-develop solutions. Unlike with previous partner labs, you may share source code, and you only need to submit it once. In other words, there is no need to type up and submit your solution twice. As I already know who your partner is, you do not need to submit a collaborators.txt file to your repository. However, if your partner arrangement changes, please let me know.

### \_\_\_\_ Reading \_\_\_\_

1. (Optional) Course packet, as needed.

# Q1. (100 points) ..... Minimal Project Prototype

For this assignment, you will build a minimally working version of your language. Along the way, you should also update your project specification.

A minimally working interpreter has the following components:

- (a) A parser. Put your parser in a library file called ProjectParser.fs. The namespace for the parser should also be called ProjectParser.
- (b) An interpreter / evaluator. Put your interpreter in a library file called ProjectInterpreter.fs.

  The namespace for the interpreter should also be called ProjectInterpreter.
- (c) A driver program. The driver should contain a main method that takes input from the user, parses and interprets it using the appropriate library calls, and displays the result. Put your main method in a file called Program.fs. For example, if your project is an infix scientific calculator (an expression-oriented language), it might accept input and return a result on the command line as follows:

```
$ dotnet run "1 + 2"
```

Alternatively, your language might read in a text file that contains the same program as above, e.g.,

```
$ dotnet run myfile.calc
```

Either way, running your language without any input should produce a helpful "usage" message that explains how to use your programming language.

```
$ dotnet run
Usage:
  dotnet run <file.calc>
```

Calculang will frobulate your foobars.

You should think carefully about what constitutes a "primitive value" in your language. Primitive values and operations on primitive values are good candidates for inclusion in a minimally working interpreter because they are generally the easiest forms of data and "combining forms" to implement.

Another form of combining form, often used in statement-oriented languages like C, is referred to as the "sequence operator", and it's what is meant by the semicolon in the the following C program fragment:

1; 2;

which produces the following AST:

where  $\epsilon$  is shorthand for "no operation." In any case, choose one combining form that makes sense in your language.

### Minimally Working Interpreter

The following constitutes a "minimally working interpreter":

- (a) Your AST can represent at least one kind of data.
- (b) Your AST can represent at least one combining form.
- (c) Your parser can recognize a program consisting of your one kind of data and your one combining form and it produces the appropriate AST.
- (d) Your evaluator can evaluate your one combining form using operands consisting of your data, and if necessary, expressions consisting of your data and combining form. In other words, it can recursively evaluate subexpressions, where appropriate. Note that it is important that your minimally working interpreter do something, whether that be to compute a value, or write to a file, etc.

#### **Minimal Formal Grammar**

Additionally, you should update your specification with a <u>formal</u> definition of the minimal grammar. For example, if our minimal working version is a scientific <u>calculator</u> that only supports addition, our first pass on the grammar might be:

Where  $_{\sqcup}$  denotes a space character and  $\epsilon$  denotes the empty string. Note that we did not write the following similar grammar.

The reason is that this latter grammar is what we call *left recursive*. In particular, the production <code><expr><ws><expr></code> is problematic for mechanical reasons: when we convert our BNF into a program (a parser), it is possible to construct a program that recursively expands the left <code><expr></code> infinitely without ever consuming any input. When using recursive descent parsers such a parser combinators, we must be careful to ensure that recursive parsers always consume some input on each step, otherwise, we run the very real danger of our parser getting stuck in an infinite loop. If your grammar is left recursive, you should redesign it so that it is no longer left-recursive.

Since your grammar only has a single combining form, precedence will not yet be an issue. However, if you can include more than one such combining form, you will need to think about the associativity of your combining form. Is it left or right associative? For example, addition is typically left associative, therefore the following expression

Be sure to explain your operator's associativity in the next section.

## **Minimal Semantics**

Finally, you should explain the semantics of your data and operators. For example, you might build the following table.

Syntax	Abstract Syntax	Type	Prec./Assoc.	Meaning
$\overline{n}$	Number of int	int	n/a	n is a primitive. We repre-
				sent integers using the 32-
				bit F# integer data type
				(Int32).
$e_1 + e_1$	PlusOp of Expr * Expr	int -> int -> int	1/left	Plus0p evaluates $e1$ and $e2$ ,
				adding their results, finally
				yielding an integer. Both
				$e_1$ and $e_1$ must evaluate
				to int, otherwise the inter-
				preter aborts the computa-
				tion and alerts the user of
				the error.
