

CSCI 334: Principles of Programming Languages

Lecture 5: The Rest of C

Instructor: Dan Barowy
Williams

Topics

Basic C

Pointers + stack model = “boxes and arrows”

Makefiles

String pitfalls

Storage duration

Call-by-value evaluation

Your to-dos

1. Lab 2, **due Sunday 2/20** (partner lab)
 - a. You may want to start the reading early
2. Reading response, **due Wednesday 2/23**.

Announcements

- Partner?
- No office hours Friday (faculty “retreat”)

Visualizing programs

1. Seeing the **program** vs. seeing the **problem**
2. It is **hard to separate feelings** from programming
 - a. Most vivid descriptions were about feeling bad during time pressure.

Growing a language

1. Isabel: Java **waiting was right** because “it was not hard to learn, and it was not hard to port.”
Scala: <https://www.scala-lang.org/api/current/scala/collectionimmutable/Vector.html>
2. Go. No generics because it was designed for the “**lowest common denominator at Google**.”

Makefiles

Makefiles

A **Makefile** is a **specification** used by the **make** tool to **automate** the compilation of programs.

Lazy
(don't want to retype)

Impatient
(don't want to wait for gcc)

Rationale

Programmers build software **frequently**.

Insight

The entire project does not need to rebuilt on every change.

```
a.h int foo (int a);  
int foo (int a) {  
    return a + 1;  
}  
  
b.h int bar (int b);  
int bar (int b) {  
    return b - 1;  
}
```

```
#include <stdio.h>  
#include "a.h"  
#include "b.h"  
  
c.c int main() {  
    int c = bar(foo(2));  
    printf("c = %d\n", c);  
    return 0;  
}
```

depends on

Insight

The entire project does not need to rebuilt on every change.

```
a.h int foo (int a);  
int foo (int a) {  
    return a + 1;  
}  
  
b.h int bar (int b);  
int bar (int b) {  
    return b - 1;  
}
```

```
#include <stdio.h>  
#include "a.h"  
#include "b.h"  
  
c.c int main() {  
    int c = bar(foo(3));  
    printf("c = %d\n", c);  
    return 0;  
}
```

depends on

depends on

make a change

a.c and b.c
do not change.

Do we really need
to rebuild them?

Makefile syntax

```
program: c.c b.o a.o  
tab→ gcc -o program c.c b.o a.o
```

```
target: dep1 ... depn  
tab→ command
```

command should produce target.

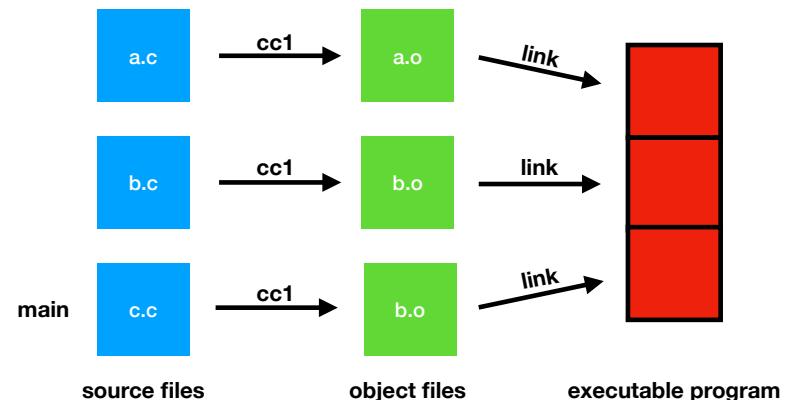

Partner activity

```
#include <stdio.h>  
  
void something(int* a, int* b) {  
    int tmp = *a;  
    *a = *b;  
    *b = tmp;  
}  
  
int main() {  
    int x = 1;  
    int y = 2;  
    something(&x, &y);  
    printf("x = %d, y = %d\n", x, y);  
    return 0;  
}
```

Produce a Makefile for this program.
Everything is in one file called something.c.

Separate compilation

Separate compilation

Makefile with separate compilation

```
#include <stdio.h>

void something(int* a, int* b) {
    int tmp = *a;
    *a = *b;
    *b = tmp;
}

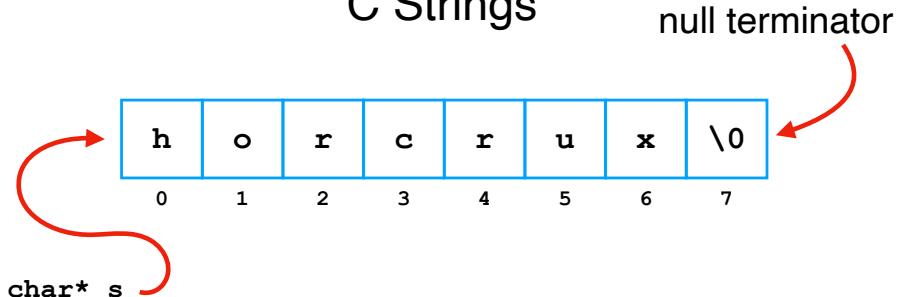

int main() {
    int x = 1;
    int y = 2;
    something(&x, &y);
    printf("x = %d, y = %d\n", x, y);
    return 0;
}
```

Split your program into **two pieces**. lib.c should contain the something function and something.c should contain main.

Update your Makefile.

More C

C Strings

C has **no string data type!**

C strings are “just” a convention.

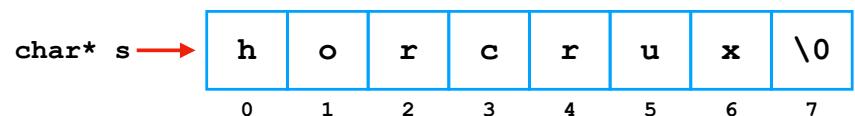

However, all string functions (`string.h`)
expect that you adhere to this convention.

Demonstration of badness

Copying Strings: watch out!

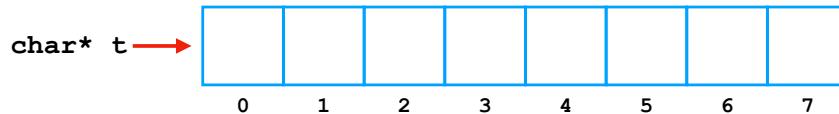

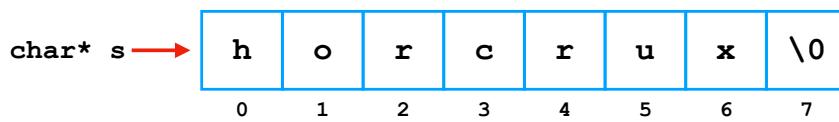

```
→ char *s = "horcrux";
char t[strlen(s)];
t = s;
```

Copying Strings: watch out!

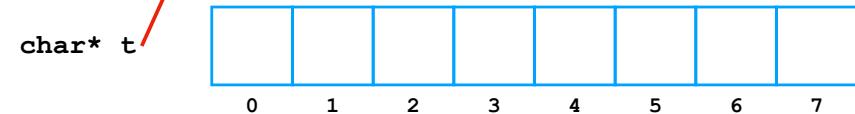

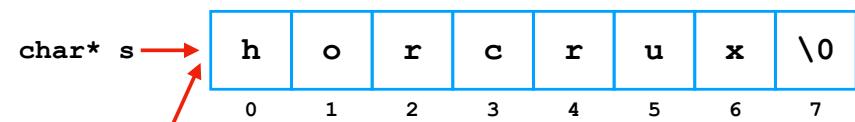

```
char *s = "horcrux";
→ char t[strlen(s) + 1];
t = s;
```

Copying Strings: watch out!

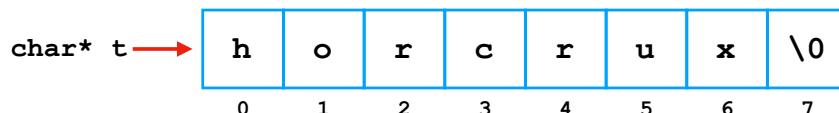

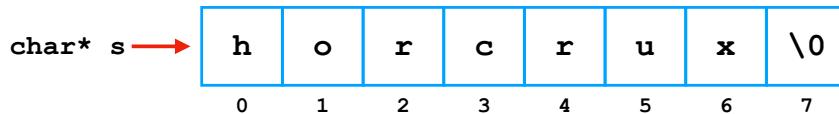

```
char *s = "horcrux";
char t[strlen(s) + 1];
→ t = s;
```

Copying Strings: watch out!

```
char *s = "horcrux";
char t[strlen(s) + 1];
→ t = s;
```

Instead, do:

```
char *s = "horcrux";
char t[strlen(s) + 1];
strcpy(t, s);
```

Storage Duration

Storage Duration

We will focus on two: **automatic** and **allocated**

You (the programmer) **choose** which one you **want**.

Rule:

Always choose **automatic duration** unless the lifetime of your data outlives its allocation site, in which case, you should choose **allocated duration**.

Storage Duration: Automatic

```
int i = 3;
```

i has **automatic** duration, because you **didn't specify a duration**.

C will automatically acquire (**allocate**) and release (**deallocate**) memory for this variable.

Nearly every C implementation stores i **on the call stack**.

Storage Duration: Automatic

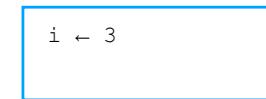

main

```
#include <stdio.h>
int main() {
    int i = 3;
    return i;
}
```

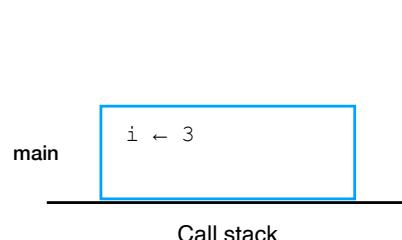

Storage Duration: Automatic

main

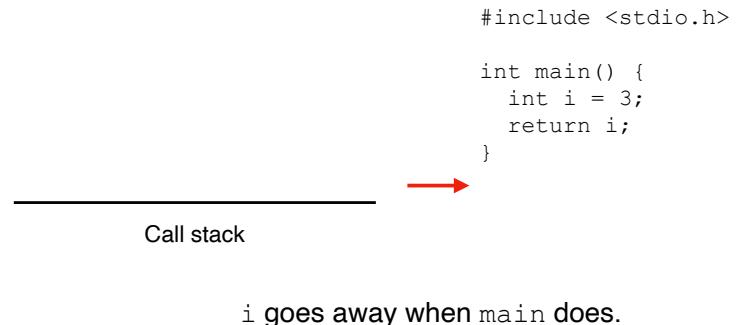

```
#include <stdio.h>
int main() {
    int i = 3;
    return i;
}
```

Storage Duration: Automatic

Storage Duration: Automatic

Storage Duration: Allocated

```
int *i = malloc(sizeof(int));
```

i has **allocated** duration, because you used **malloc**.

C will manually **allocate on request** and **deallocate** memory **on request**.

Nearly every C implementation stores i **on the heap**.

Storage Duration: Allocated

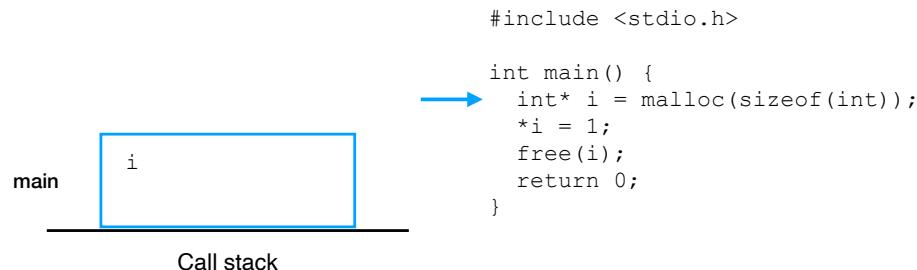

To **deallocate**, you must call **free**

```
int *i = malloc(sizeof(int));
free(i);
```

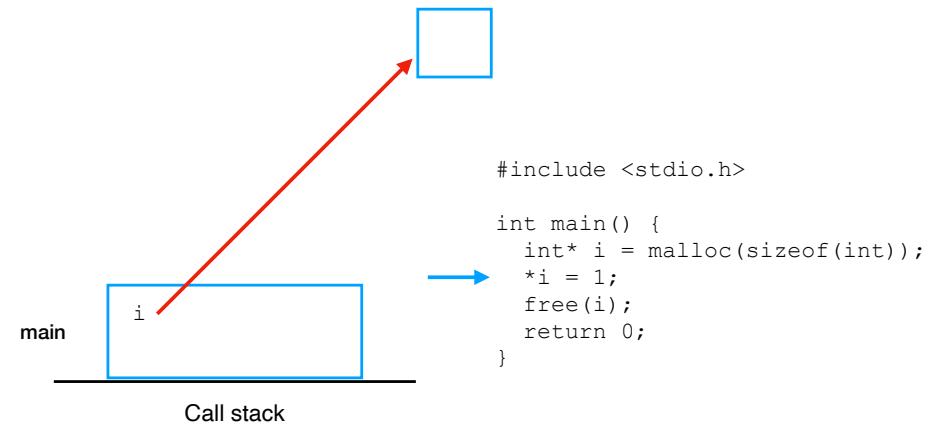

You have to do this even if i goes out of scope!

Failing to free when you are done is a **bug** called a **memory leak**.

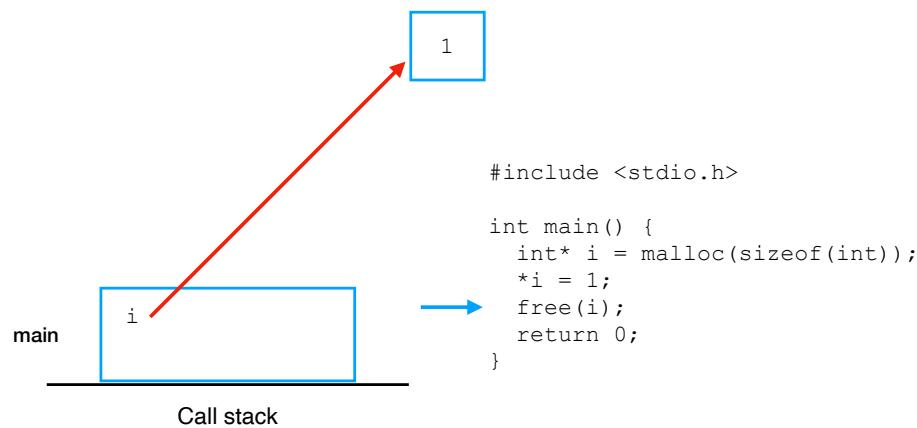

Storage Duration: Allocated

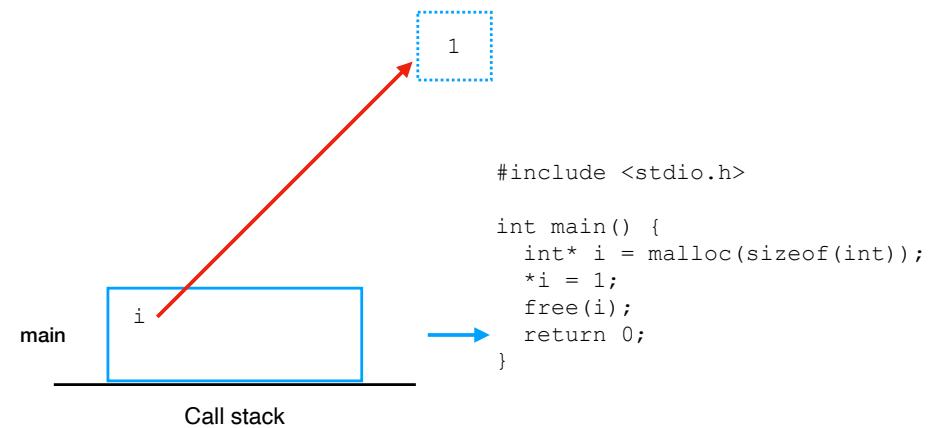

Storage Duration: Allocated

Storage Duration: Allocated

Storage Duration: Allocated

free **does not erase** the value stored in memory.

free **does not nullify** the pointer stored in `i`.

All `free` does is **mark** the allocated memory as "**Reusable**."

Person example

```
#include <stdio.h>
#include <stdlib.h>

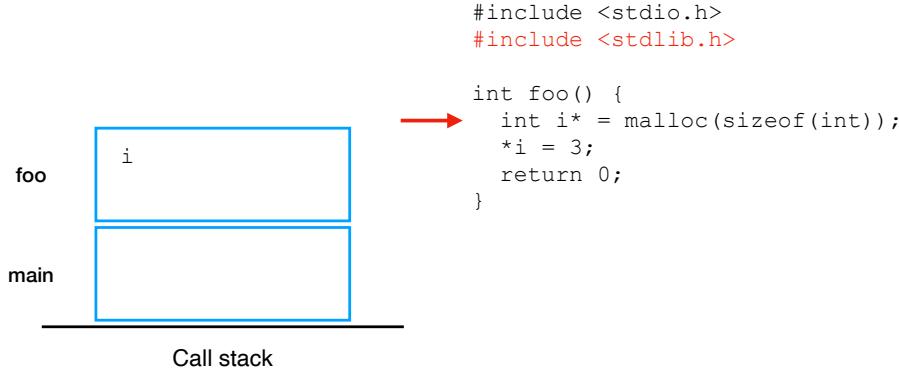

struct person {
    char* fname;
    char* lname;
};

struct person* makePerson(char* first_name, char* last_name) {
    struct person* p = malloc(sizeof(struct person));
    if (!p) {
        fprintf(stderr, "Unable to allocate person.\n");
        exit(1);
    }
    p->fname = first_name;
    p->lname = last_name;
    return p;
}

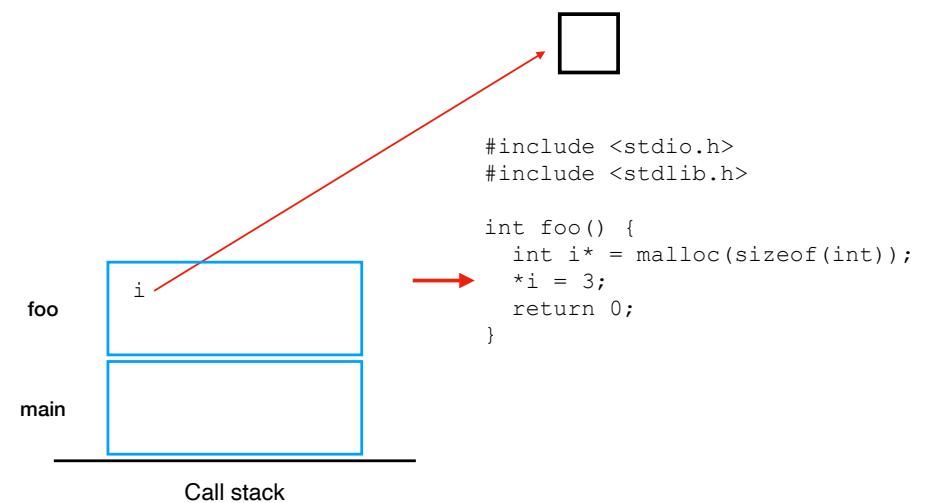

int main(int argc, char** argv) {
    if (argc != 3) {
        printf("Usage:\n\t./person <first name> <last name>\n");
        exit(1);
    }

    struct person* p = makePerson(argv[1], argv[2]);
    printf("First name = '%s', Last name = '%s'\n", p->fname, p->lname);
    free(p);
    return 0;
}
```

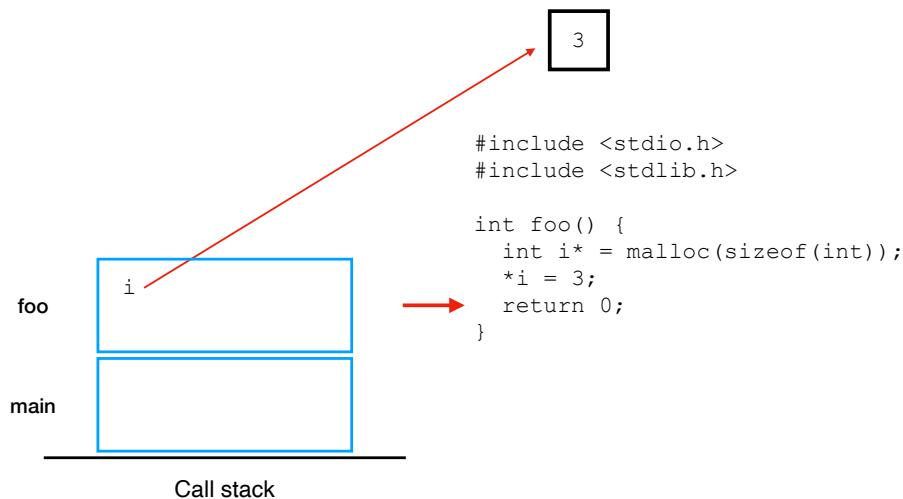

Allocated Duration Pitfalls

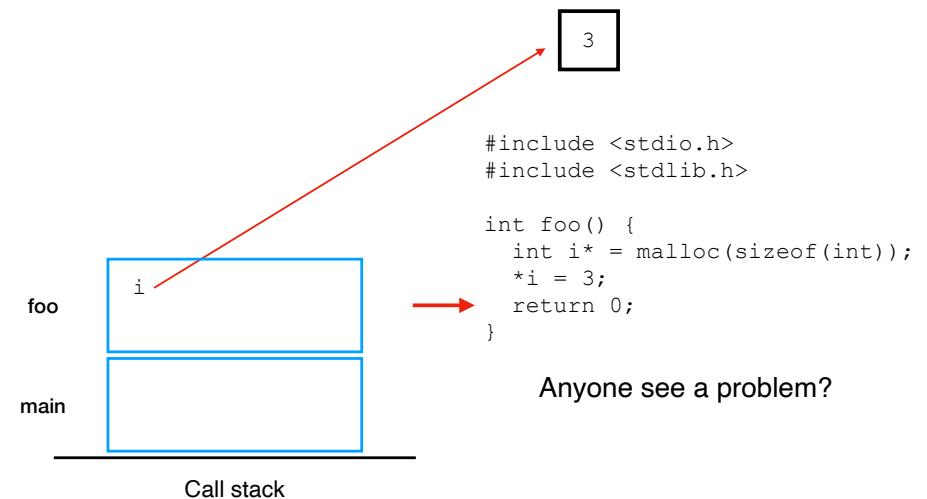

Allocated Duration Pitfalls

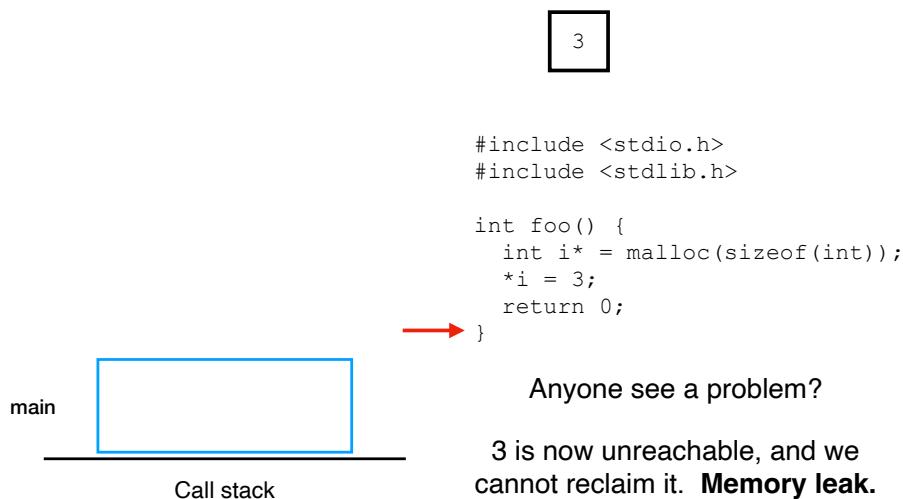

Allocated Duration Pitfalls

Allocated Duration Pitfalls

Allocated Duration Pitfalls

Call-by-value

(program evaluation strategy)

Examples:

C
Java
Python

```

#include <stdio.h>

int add(int x, int y) {
    int z = x + y;
    return z;
}

int main() {
    int x = 1;
    int z = add(x, 3);
    return z;
}

```

How does a function “obtain” a parameter value?

When using call-by-value semantics: **copying**

Call-by-value

```

#include <stdio.h>

int add(int x, int y) {
    int z = x + y;
    return z;
}

int main() {
    int x = 1;
    int z = add(x, 3);
    return z;
}

```

Call stack

Call-by-value

main

x
z

Call stack

```

#include <stdio.h>

int add(int x, int y) {
    int z = x + y;
    return z;
}

int main() {
    int x = 1;
    int z = add(x, 3);
    return z;
}

```

main

x = 1
z

Call stack

Call-by-value

```

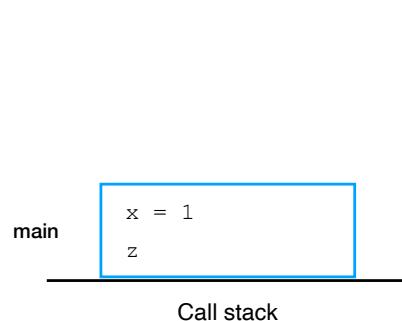

#include <stdio.h>

int add(int x, int y) {
    int z = x + y;
    return z;
}

int main() {
    int x = 1;
    int z = add(x, 3);
    return z;
}

```

Call-by-value

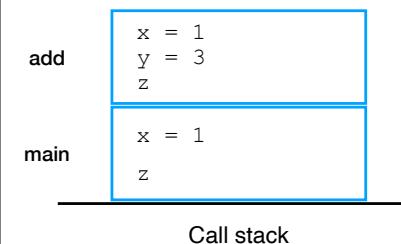

```
#include <stdio.h>

int add(int x, int y) {
    int z = x + y;
    return z;
}

int main() {
    int x = 1;
    int z = add(x, 3);
    return z;
}
```

Call-by-value

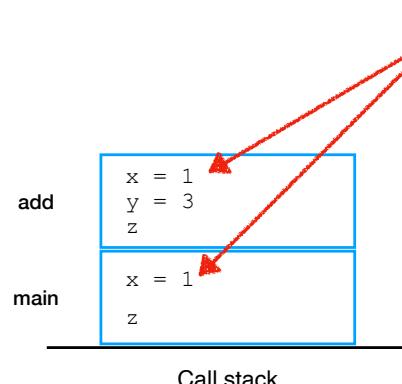

```
#include <stdio.h>

int add(int x, int y) {
    int z = x + y;
    return z;
}

int main() {
    int x = 1;
    int z = add(x, 3);
    return z;
}
```

Call-by-value

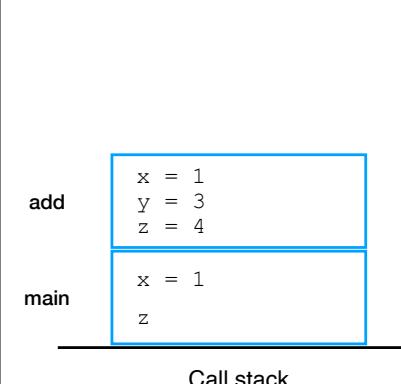

Not the same x!

```
#include <stdio.h>

int add(int x, int y) {
    int z = x + y;
    return z;
}

int main() {
    int x = 1;
    int z = add(x, 3);
    return z;
}
```

Call-by-value

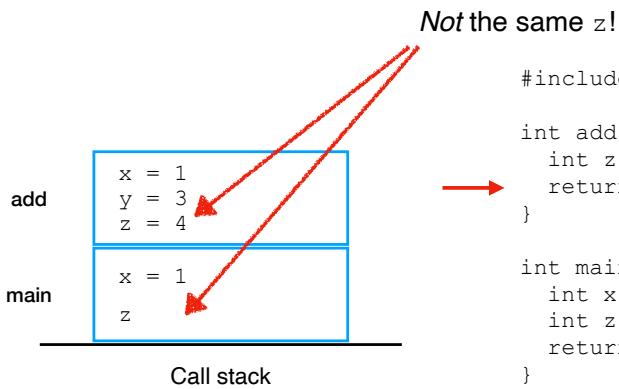

```
#include <stdio.h>

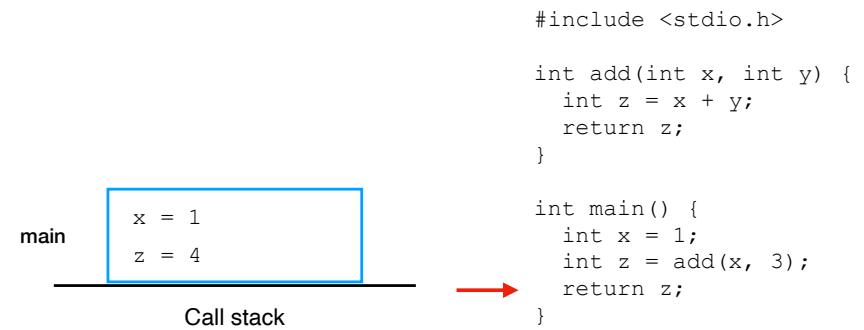

int add(int x, int y) {
    int z = x + y;
    return z;
}

int main() {
    int x = 1;
    int z = add(x, 3);
    return z;
}
```
