Principles of Programming Languages

Lecture 6: The Dream of Computation

Instructor: Dan Barowy

Williams

Topics

Pointers: the key to abstraction

The dream

Backus-Naur form

Lambda calculus—what it is

Your to-dos

1. Reading response, **due Wednesday 2/23**.
2. Lab 2, **due Sunday 2/27** (individual lab)

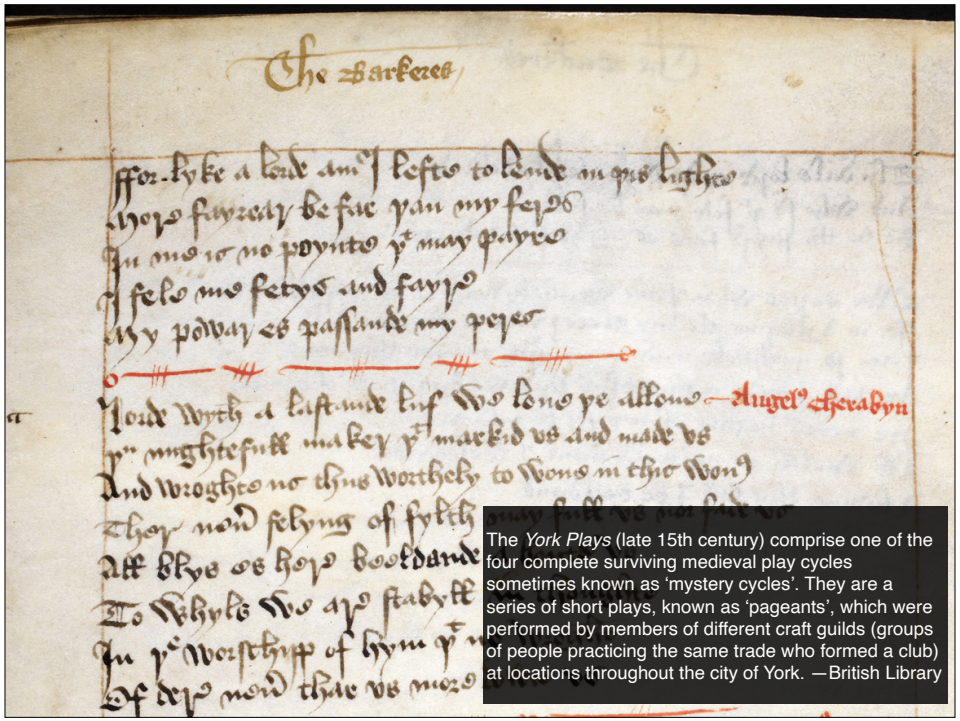
Announcements

- **Friday colloquium**, senior thesis proposals #2, 2:35pm in Wege Auditorium
- Masking: what do you think? **Survey.**

What can a function return?

What can a function return?

Pointers are "little."



The *York Plays* (late 15th century) comprise one of the four complete surviving medieval play cycles sometimes known as 'mystery cycles'. They are a series of short plays, known as 'pageants', which were performed by members of different craft guilds (groups of people practicing the same trade who formed a club) at locations throughout the city of York. —British Library

Why couldn't you understand the script?

It's written in English, after all!

We don't know the "ground rules" for the document as it is written:

- Appearance: **syntax**
  - What is the set of valid **symbols**?
  - What **arrangements** of symbols are permissible?
- Meaning: **semantics**
  - What does **a given arrangement** of symbols correspond **mean**?

Formal language

A **formal language** is the set of permissible **sentences** whose **symbols** are taken from an **alphabet** and whose word **order** is determined by a specific set of **rules**.

Intuition: a language that can be defined mathematically, using a **grammar**.

English **is not** a formal language.

Java **is** a formal language.

More formally

L(**G**) is the set of all sentences (a "language") defined by the grammar, **G**.

G = (**N**, **Σ**, **P**, **S**) where

N is a set of nonterminal symbols.

Σ is a set of terminal symbols.

P is a set of production rules of the form
N ::= (**Σ**∪**N**)*
where * means "zero or more" (Kleene star) and
where ∪ means set union

S∈**N** denotes the "start symbol."

Backus-Naur Form (BNF)

More concretely, for programming languages, we conventionally write **G** in a form called **BNF**.

John Backus

Peter Naur

Invented in 1959 to describe the ALGOL 60 programming language.

Tower of Hanoi (ALGOL 60)

```
begin
  procedure movedisk(n, f, t);
  integer n, f, t;
  begin
    outstring (1, "Move disk from");
    outinteger(1, f);
    outstring (1, "to");
    outinteger(1, t);
    outstring (1, "\n");
  end;

  procedure dohanoi(n, f, t, u);
  integer n, f, t, u;
  begin
    if n < 2 then
      movedisk(1, f, t)
    else
      begin
        dohanoi(n - 1, f, u, t);
        movedisk(1, f, t);
        dohanoi(n - 1, u, t, f);
      end;
  end;

  dohanoi(4, 1, 2, 3);
  outstring(1,"Towers of Hanoi puzzle completed!")
end
```

Backus-Naur Form (BNF)

Nonterminals, **N**, are in brackets: `<expression>`

Terminals, **Σ**, are "bare": `x`

A production rule, **P**, consists of the `::=` operator, a nonterminal on the left hand side, and a sequence of one or more symbols from **N** and **Σ** on the right hand side.

```
<variable> ::= x
```

The `|` symbol means "alternatively": `<num> ::= 1 | 2`

We use ε to denote the empty string nonterminal.

Backus-Naur Form (BNF)

You should read the following BNF expression:

```
<num> ::= <digit>
        |  <num><digit>
```

as

"`num` is defined as a `digit` or as a `num` followed by a `digit`."

Backus-Naur Form (BNF)

The following definition might look familiar:

```
<expr>   ::= <num>
           |  <expr> + <expr>
           |  <expr> - <expr>
<num>    ::= <digit>
           |  <num><digit>
<digit>  ::= 0|1|2|3|4|5|6|7|8|9
```

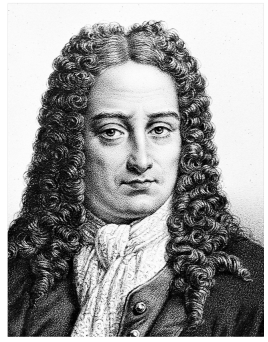
`<expr>` is the start symbol.

Conventionally, we ignore whitespace, but if it matters, use the ␣ symbol. E.g.,

`<expr>␣+␣<expr>`

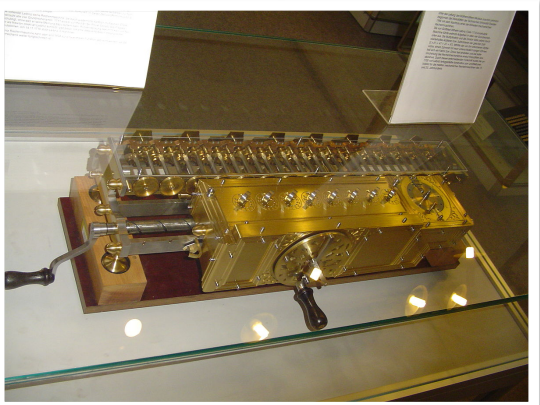
The Dream

"I thought again about my early plan of a new language or writing-system of reason, which could serve as a communication tool for all different nations... If we had such an universal tool, we could discuss the problems of the metaphysical or the questions of ethics in the same way as the problems and questions of mathematics or geometry. That was my aim: Every misunderstanding should be nothing more than a miscalculation (...), easily corrected by the grammatical laws of that new language. Thus, in the case of a controversial discussion, two philosophers could sit down at a table and just calculating, like two mathematicians, they could say, 'Let us check it up …'"



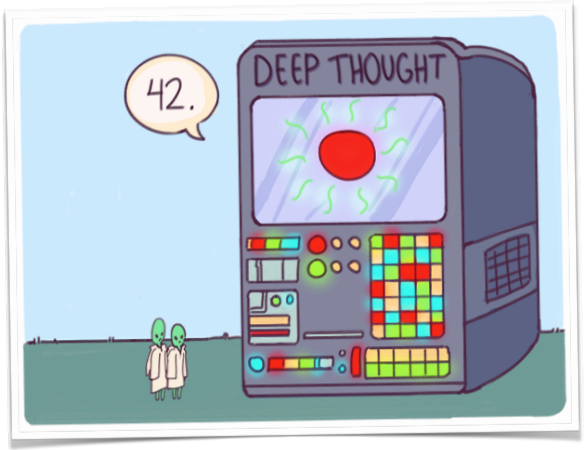
Wilhelm Gottfried Leibniz

The Dream



"stepped reckoner"

Wilhelm Gottfried Leibniz



"What is the answer to the ultimate question of life, the universe, and everything?

What is computable?

- Hilbert: Is there an algorithm that can decide whether a logical statement is valid?
- "Entscheidungsproblem" (literally "decision problem")
- Leibniz thought so!

What is computable?

- Why do we care?
- f(x) = x + 1
- We can clearly do this with pencil and paper.
- $\int 6x\,dx$
- Also computable, in a different manner.
- We care because the computable functions can be done on a computer.

Lambda calculus

- Invented by Alonzo Church in order to solve the Entscheidungsproblem.
- Short answer to Hilbert's question: no.
- Proof: No algorithm can decide equivalence of two arbitrary λ-calculus expressions.
- By implication: no algorithm can determine whether an arbitrary logical statement is valid.

What is the meaning of `x` in **algebra**?

Pro tip

Don't try to "**understand**" the lambda calculus.

Aside from "**variable**," "**function definition**," and "**application**," it has no inherent meaning.

We **ascribe meaning** to it, just as we do with algebra.

The lambda calculus is simply a **system** for reasoning by using **the logic of functions**.

Lambda calculus grammar

```
<expr>   ::= <var>
           |  <abs>
           |  <app>
<var>    ::= x
<abs>    ::= λ<var>.<expr>
<app>    ::= <expr><expr>
```

`<expr>` is the start symbol.

What is a variable?

```
<var>    ::= x
```

It's just a value.

What is an abstraction?

```
<abs>    ::= λ<var>.<expr>
```

It's a function definition

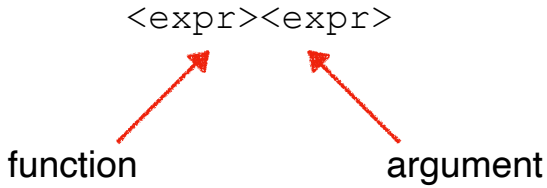
```
def foo(x):
  <expr>
```

What is an application?

```
<app>    ::= <expr><expr>
```

It's a "function call"

```
foo(2)
```



Parsing and Parse Trees

Parsing is the process of analyzing a string of symbols, conforming to the rules of a formal grammar, to understand:

1) whether that sentence is valid (**s** ∈ L(**G**)), or
2) the structure (e.g., "parts of speech") of that sentence (a **parse tree**).

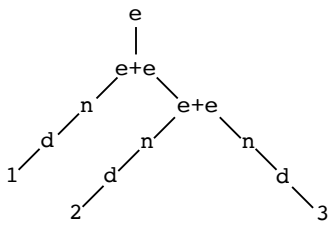
There are at least **two forms** of trees that we might refer to "parse trees"

Derivation Tree

Shows **every step** of how a sentence is **parsed**.

```
e ::= n | e+e | e-e
n ::= d | nd
d ::= 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9
```

1+2+3

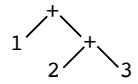


Abstract Syntax Tree

Ignores derivation details; only **essential structure**

```
e ::= n | e+e | e-e
n ::= d | nd
d ::= 0 | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9
```

1+2+3

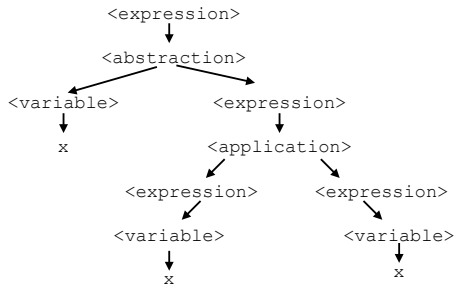


In an **AST**, internal nodes are **operations**, leaves are **data**.

Parse tree

We can create a “derivation tree” by following the rules of a grammar as we interpret a sentence of a language.

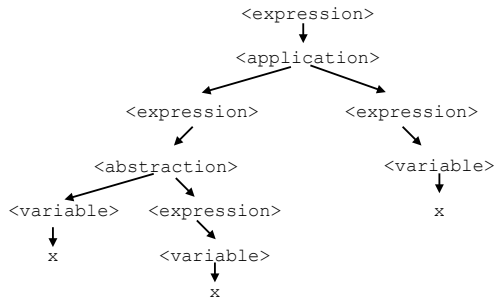
λx.xx



Abiguity

You might have noticed that there is an alternative parse tree.

λx.xx



Abiguity

In fact, the lambda calculus is never ambiguous because of its precedence and associativity rules—next class.

Parentheses disambiguate grammar

<expr> = (<expr>)

Axiom of equivalence for parens

Let's modify our grammar

Lambda calculus grammar

```
<expr>   ::= <var>
           | <abs>
           | <app>
           | <parens>
<var>    ::= x
<abs>    ::= λ<var>.<expr>
<app>    ::= <expr><expr>
<parens> ::= (<expr>)
```

While we're at it…

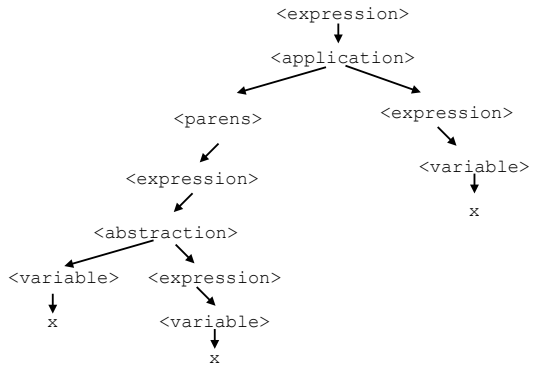
```
<expr>   ::= <var>
           | <abs>
           | <app>
           | <parens>
<var>    ::= α ∈ { a ... z }
<abs>    ::= λ<var>.<expr>
<app>    ::= <expr><expr>
<parens> ::= (<expr>)
```

Also…

```
<expr>   ::= <value>
           | <abs>
           | <app>
           | <parens>
<var>    ::= α ∈ { a ... z }
<abs>    ::= λ<var>.<expr>
<app>    ::= <expr><expr>
<parens> ::= (<expr>)
<value>  ::= v ∈ ℕ
           | <var>
```

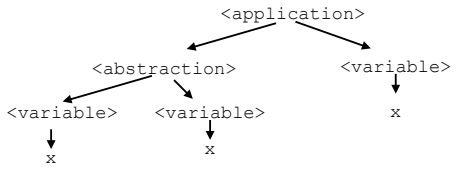
This expression is now unambiguous

$(\lambda x.x)\,x$



However, this is the parse tree we really care about

$(\lambda x.x)\,x$



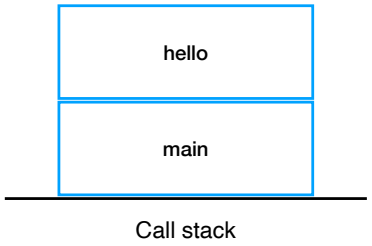
Free vs bound variables

$(\lambda x.x)\,x$

bound free

Next class: evaluation

Evaluation: You know how C does it



```
#include <stdio.h>

void hello() {
  printf("Hello world!\n");
}

int main() {
  hello();
  return 0;
}
```

Evaluation: Lambda calculus is like algebra

$(\lambda x.x)\,x$

Evaluation consists of simplifying an expression using text substitution.

Recap & Next Class
